

ISMS Boundaries and Interfaces

Document ID: ISMS-BND-001 | Version: 1.0 | Status: Draft for Portfolio Simulation | Date: 11 August 2026

1. Boundary Model

The ISMS boundary is defined using organizational, physical, technological, informational and supplier interfaces. The boundary is intended to capture the assets and activities that can materially influence the confidentiality, integrity or availability of in-scope information.

2. Boundary Table

Boundary	Included / Interface
Organizational	Employees, management, IT, development, operations, customer support and relevant corporate functions
Physical	Corporate work areas and employee work environments where in-scope information is accessed; third-party data-centre
Technological	Cloud infrastructure, production systems, endpoints, identity systems, source-code repositories, business applications,
Information	Customer, employee, financial, operational, source-code, credential and security-related information
Suppliers	Cloud providers, SaaS providers, telecommunications providers and other suppliers supporting in-scope processes
Customers	Customer-facing interfaces and contractual security requirements affecting the SaaS service

3. Key Interfaces

The most significant interfaces are between TechNova employees and corporate systems; development teams and source-code repositories; operations teams and cloud infrastructure; customers and SaaS applications; and TechNova and third-party suppliers.

4. Boundary Control Principle

Where an activity or asset is outside TechNova's direct operational control but can affect the ISMS, the organization manages the relationship through supplier assessment, contractual requirements, monitoring, risk treatment and other appropriate controls.
